#### LEC013 Greedy: Scheduling, MST

#### VG441 SS2021

Cong Shi Industrial & Operations Engineering University of Michigan

## **Scheduling Problem**

- We are given n jobs to schedule
- For each job j = 1, ..., n, let
  - $w_i$  be the weight (or the importance)
  - $l_i$  be the length (or the time required)

• Define the completion time of job j  $c_j = \text{sum of the lengths of jobs up to and including } l_j$ 

Objective: to minimize the weighted sum of completion times

$$\sum_{j=1}^{n} w_j \cdot c_j$$

#### Intuition

- If all jobs have the same length, we prefer larger weighted jobs to appear earlier in the order
- If all jobs have equal weights, we prefer shorter length jobs to appear earlier in the order

$$w_i = 1 \ \forall i$$
 2 1

$$w_1c_1 + w_2c_2 + w_3c_3 = 3 + 5 + 6 = 14$$

### Quandrum (Tricky Cases)

What do we do in the cases where

$$l_i < l_j \text{ and } w_i < w_j$$

 Idea: give a priority score (prefers smaller length and larger weight at the same time)

score-diff 
$$= l_j - w_j$$
 Guess #1 
$$\text{score-ratio} = l_j/w_j$$
 Guess #2

# Quandrum (Tricky Cases)

• Let a look at a simple example:  $l_i < l_j \text{ and } w_i < w_j$ 

Score-diff does not work so well...

score-diff =  $l_j - w_j$  2 1 WC = 2 + 21 = 23

Score-ratio seems to work

score-ratio =  $l_j/w_j$  1 2 WC = 15 + 7 = 22

#### **Correctness Argument**

- Claim: Ranking by score\_ratio is correct.
- Proof (by exchange argument):

Consider some input of *n* jobs, now rename the jobs according the score\_ratio, then our greedy algo picks the schedule

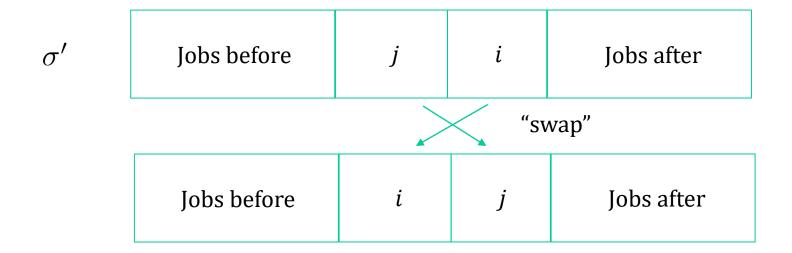

$$\sigma = 1, 2, 3, \dots, n \text{ with } \frac{l_1}{w_1} \le \frac{l_2}{w_2} \le \frac{l_3}{w_3} \le \dots \le \frac{l_n}{w_n}$$

#### **Correctness Argument**

• Consider any other schedule  $\sigma'$ , we want to show that  $\sigma$  is as good as  $\sigma'$ 

Now if  $\sigma' \neq \sigma$  then at some point in  $\sigma'$ , there exists a job i right after a job j with i < j (why?)

#### **Correctness Argument**

$$WC^{\text{after swap}} - WC^{\text{before swap}} = w_j l_i - w_i l_j \le 0$$

After at most (n-choose-2) steps, we recover our greedy  $\,\sigma\,$  with at least good as  $\,\sigma'\,$ 

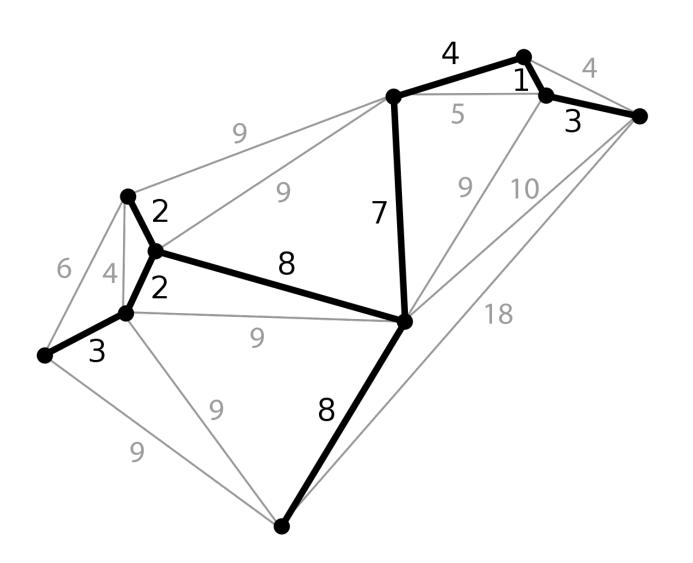

#### **MST**

Given undirected connected graph, G = (V, E). There is a function  $c : E \to \mathbb{R}$ , showing the cost of each edge. Assume that there are m edges in G

Definition (tree):  $T = (V_T, E_T)$ , is an undirected graph in which any two vertices are connected by exactly one path. In other words, any acyclic connected graph is a tree.

Definition (a spanning tree):  $T = (V_T, E_T)$  in graph G = (V, E) is a tree with  $E_T \subseteq E$  that has all vertices covered, i.e.  $V_T = V$ 

# An Example of MST

# Greedy Algorithm for MST (Kruskal Algo)

- 1. sort edges in non-decreasing order of cost,  $c(e_1) \le c(e_2) \le \cdots \le c(e_m)$
- 2. Let  $T_1 = \emptyset$
- 3. For  $i = 1, 2, \dots, m$ , if  $(T_i \cup \{e_i\})$  contains no cycle, let  $T_{i+1} = T_i \cup \{e_i\}$

We apply quicksort to assign indices to edges in the first step. We can apply a simple check of whether there is a cycle in graph  $T_i \cup e_i$  in step 3

- 1. Get both ends of edge  $e_i$ , vertex a and b
- 2. Make a list L that contains all vertices connected to a in  $T_i$
- 3. If vertex b is in L, there will be a cycle in  $T_i \cup \{e_i\}$  . If b is not in L, then  $T_i \cup \{e_i\}$  is acyclic.

Note that the algorithm above takes O(m) time. So the overall greedy algorithm runs in polynomial time.

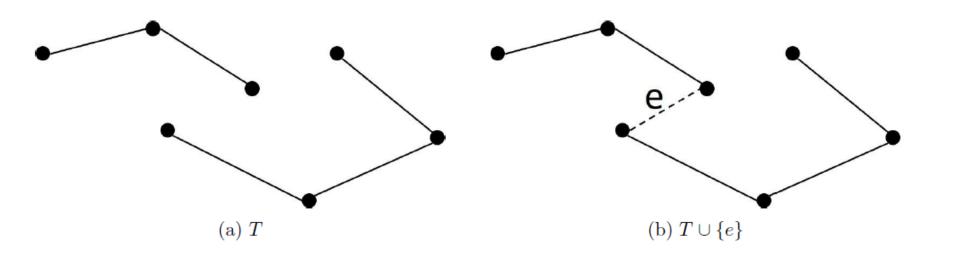

#### **Python Code**

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree
>>> X = csr matrix([[0, 8, 0, 3],
                    [0, 0, 2, 5],
                    [0, 0, 0, 6],
                    [0, 0, 0, 0]])
. . .
>>> Tcsr = minimum_spanning_tree(X)
>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

#### **Analysis**

**Lemma:** The algorithm gives a tree T that covers all vertices in G.

**Proof:** Given the graph is connected, we can prove this property by contradiction. If in the tree T generated by algorithm, not all the vertices are connected, there exist an edge  $e \in E$  between two disconnected components of T (see Figure 1 a). Because T is acyclic, and two components are not connected, we can declare that  $T \cup \{e\}$  is also acyclic. Then according to the algorithm, e must have been included.

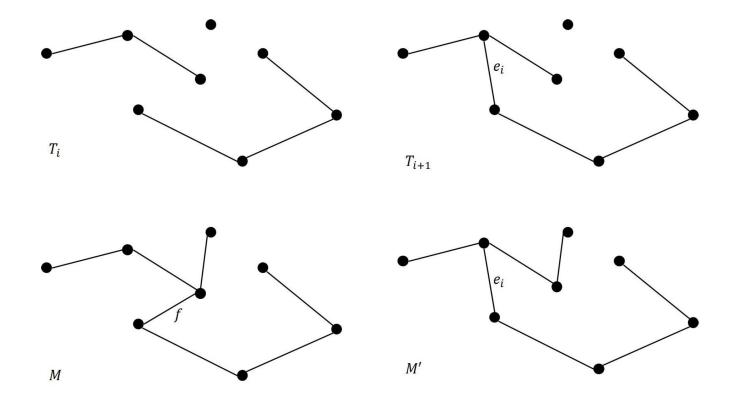

#### **Analysis**

Let  $i = 1, 2, \dots, m, m + 1$  denote the iteration in the algorithm. Let  $T_i$  denote the solution at the beginning of  $i^{th}$  iteration.

**Lemma:** For each iteration i, there is a minimum spanning tree M with  $T_i \subset M$ 

Quandrum (tricky case)

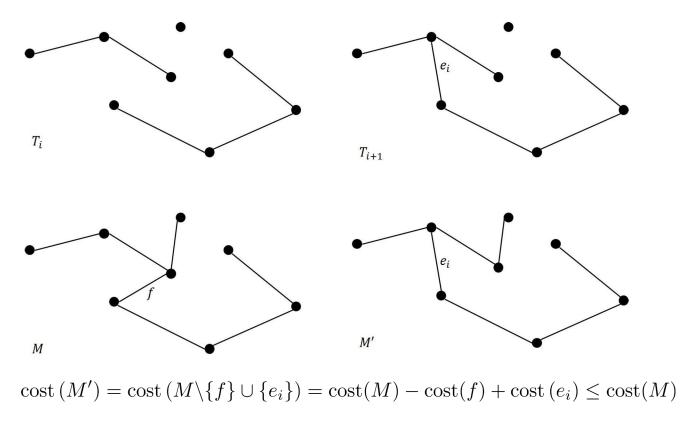

Suppose  $T_i \subseteq M$  but  $T_{i+1} = T_i \cup \{e_i\} \nsubseteq M$ 

$$cost(M') = cost(M \setminus \{f\} \cup \{e_i\}) = cost(M) - cost(f) + cost(e_i) \le cost(M)$$

#### **Analysis**

Suppose  $T_i \subseteq M$  but  $T_{i+1} = T_i \cup \{e_i\} \nsubseteq M$ 

- $M \cup e_i$  must contain a cycle (if not, then M is disconnected.)
- There must be an edge f in this cycle that is costlier than  $e_i$  (if not, then the greedy algorithm would not pick  $e_i$ )
